Phase 1: Requirement Analysis & Planning

1. Current State Problem Statement

The school IT helpdesk receives multiple support requests daily from students and teachers related to common operational issues such as network connectivity, hardware failures, account access problems, and system performance limitations.

Currently, the internal IT staff must manually review each individual incoming ticket to perform the following tasks:

- **Identify issue parameters:** Determine the underlying root problem type based on user notes.
- **Categorization:** Manually map and select the accurate category and subcategory classifications.
- **User Communication:** Send standard notification alerts informing the caller regarding manual ticket registration.

CRITICAL BLOCKER: *This current manual pipeline execution model is inherently time-consuming, highly error-prone, and lacks architectural scalability as the total inbound request volume scales exponentially.*

2. Activity 1: Business Use Case & System Requirements

To completely eliminate manual dependencies and systematically automate helpdesk workflows, the modern ServiceNow architecture must explicitly fulfill the target business requirements detailed below:

Requirement Parameter	<ParagraphStyle 'H_D'>
Automated Classification	The cloud platform must intelligently parse textual issue descriptions to dynamically determine context and classify incoming records automatically.
Zero-Touch Assignment	Assign both the baseline system Category and dependent Subcategory values flawlessly without requiring manual field modifications from triage technicians.
Dependent Choice Logic	Enforce strict conditional dynamic choice listing matrices between parental Category data fields and nested downstream child Subcategory options.
Instant Notifications	Construct automated transaction engine triggers to transmit a validation confirmation dispatch email directly to the caller immediately upon standard record generation.
Structured Storage	Archive all transaction parameters safely inside clean, canonical relational tables designed under standardized platform schematics.

Scalability Architecture	Implement scalable low-code system footprints supporting streamlined ongoing management, modular extension, and dynamic expansion capabilities.

3. Activity 2: Configuration of Local Update Set Environment

To track system updates cleanly across application workspaces, apply the following step-by-step configuration workflow setup directly within the target ServiceNow instance workspace instance environment:

Step 1: Navigate to the main application interface panel, select the **All Application Menu** router, and execute a text lookup search queries filter matching *Update Set*.

Step 2: Locate the core module block labelled **System Update Sets** and click the nested **Local Update Sets** list management module context index.

Step 3: Execute an initialization command by clicking the primary **New** button control anchored layout view window at the top right structural margin.

Step 4: Populate the system transaction record creation parameters inside the initialization workspace profile layout context sheet as follows:
• **Name:** Project Update Set
• **State:** In progress
• **Application Scope:** Global

Step 5: Commit your data modifications directly to the database layer by executing a standard form layout context click command on the **Submit** action button.

Step 6: Scroll to view context components under the secondary lower **Related Links** collection frame layout menu index link, then interact with the action query labelled **Make This My Current Set**.

Step 7: Verify deployment operation validation status parameters by checking that the newly committed record now successfully defaults as your active workspace system configuration tracker environment profile.

4. Activity 3: Technical Form Layout & UI Navigation Validation Matrix

The visual confirmation layout diagrams capture deployment environment states confirming clean local tracking structure creation workflows:

• **Top Target Form Panel (Local Update Set Canvas):** Validates active property layout configurations. Shows the tracking tracker name initialized to Project Update Set, *In progress* tracking status flag metrics, and target *Global* platform visibility. The baseline frame highlights active configuration links pointing to current workspace tracker initialization scripts.

- **Bottom Target Studio View (Development Application Workspace):** Captures visual confirmation validation maps within ServiceNow Studio development environment interface trees. Confirms proper functional scope links linking ongoing cloud development tasks into the active local update set tracker package matrix workspace.
